ABSTRACT

This paper provides an overview of the changes in deepwater and ultra-deepwater definitions, the evolutions in drilling rigs, well design, drilling and completion practices, and equipment to overcome many unique challenges and high drilling costs. Oil and gas drilling and development in deepwater and ultra-deepwater have been around for more than 60 years and become more and more important to the global petroleum industry. With each advancement in technology, we can explore and produce hydrocarbons further offshore, at deeper water depths, and thus the definitions of deepwater and ultra deepwater have been repeatedly rewritten. This segment of the petroleum industry has experienced the highest growth and number of innovations thanks to many giant deepwater discoveries turned into productive fields in the Gulf of Mexico, Brazil, North Sea, West Africa, and elsewhere throughout the world. With more and more wells drilled at ever increasing water depth, the drilling challenges, including both natural and operations hazards increase exponentially, which result in more and more stringent technical requirements for a safe operation. These are being met by the rapid and complicated evolution of BOPs and drillships over several generations, optimization of deepwater big bore well design, and applications of drilling and completion, marine navigation, ROV technologies and procedures, and sharing of lessons learned. This demonstrates the industry's continued and focused interest in the process of enabling resources extraction from this environment of deep and ultra-deep water, especially to combat the high risks and high investment costs for deep and ultra-deep water projects, in which drilling cost is the most significant share. In the second section, the paper looks at the hydrocarbon potentials of Vietnam deepwater and ultra deepwater, the current status, and the various challenges, and proposes required steps to enable Vietnam to tap in this vast unexplored hydrocarbon resources.

Key words: Deepwater drilling, evolutions of drilling, well design, deepwater drilling in VietNam, Vietnam deepwater challenges, Vietnam deepwater drilling status, lessons for Vietnam

1 INTRODUCTION

2 Deepwater and ultra deepwater definitions

The definitions of deepwater and ultra-deepwater have changed significantly and often with advances in our industry's capabilities and technology. In the 1970s, a water depth above 200m, off the operational limit of jack-up rigs, was regarded as deepwater¹. In the '70s and '80s, a water depth limit up to 1,000m could be reached with fixed drilling and production platforms². Later in the '90s and early 2000s these depths can be drilled from spars, tension leg platforms, or by using 4th- and 5th-generation semisubmersibles and drillships. Thus, water depths below 800m- 1200m have become "legacy" deepwater, and now considered "mid water depth.". In the 2000s, the developments of 6th generation semi-submersibles and drillships further pushed the operational water depth to over 3,000m². And within the last ten years,

the latest 7th and 8th generation drillships can operate at water depth up to 3,650m (12,000ft)³. Figure 1 shows the development of drillships throughout the years and the ever increasing water depth they can operate.

In this context, we will define "deepwater" for water depths dominantly can only be drilled by semi-submersibles and drillships, currently starting at around 800m - 1,200m (4,000ft). "Ultra-deepwater" is defined for water depths over 2,300m (7,500ft), where new set of drilling challenges emerge that only recent generation semi-submersibles and drillships can handle, for example with the use of Dynamic Position System, dual-derrick technologies.

Drilling rigs for drilling in deepwater

Semi-submersibles and drillships are expensive floating-type rigs equipped with dynamic positioning systems (DPS) that allow them to stay stable, directly

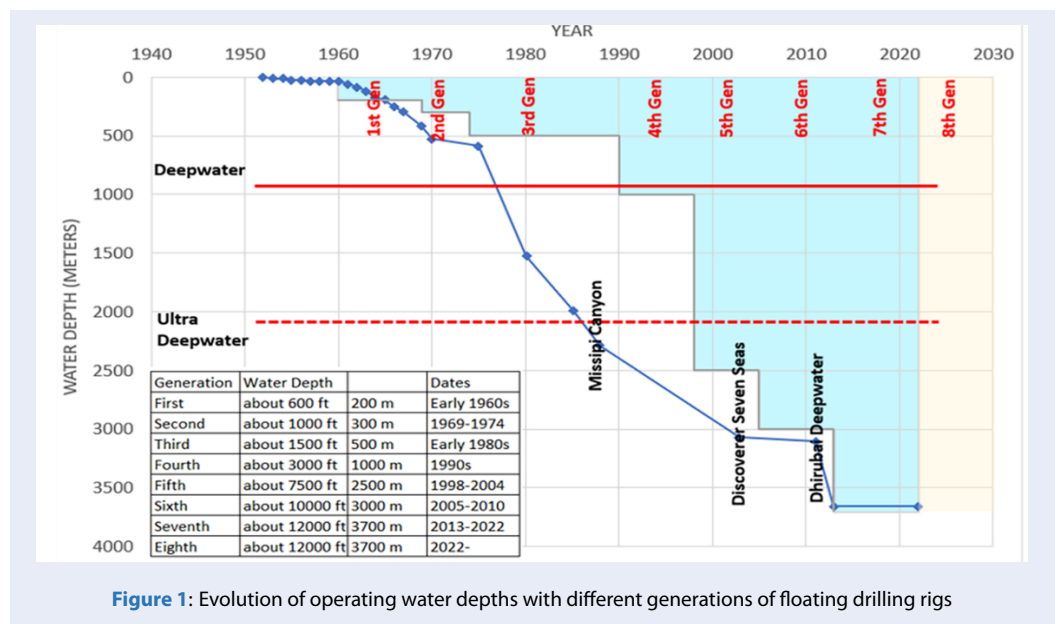

Figure 1: Evolution of operating water depths with different generations of floating drilling rigs

37 above the drilling sites against sea currents, winds,
 38 and waves, although when operating in shallower
 39 water depths the DPS can also be aided by mooring.
 40 Rig moves are much faster
 41 than fixed drilling rigs. A semisubmersible has legs or
 42 pontoons that are partially immersed in water to help
 43 the rig's top stay afloat. It has a huge deck space, so
 44 big that in 2021 SpaceX bought two decommissioned
 45 semisubmersible rigs with plans to convert them into
 46 floating launchpads for its enormous 120-meter-tall
 47 Starship rockets⁴. On the other hand, a drillship re-
 48 quires no towing and is unique by having a hole in
 49 the ship's structure from the main deck through the
 50 hull called moonpool. Currently, drillships are the
 51 preferred choice for far-flung locations and demand
 52 top dollars for their day rate. At the time of writing
 53 this paper (Q3/2023), there have been only two 8th
 54 generation drillships built and in operation.

55 Figure 2 shows examples of semi-submersibles and
 56 drillships of different generations. Dual-derrick, op-
 57 erating water depth to 3,600m (12,000ft), 40,000ft
 58 drilling depth, 15k-20k psi BOP, or hoisting capac-
 59 ity over 2.5 million pounds are some technical at-
 60 tributes that distinguish new generation deepwater
 61 drilling rigs to their older generation companions.
 62 These specifications allow these drilling rigs to over-
 63 come the myriad of challenges when drilling in deep
 64 and ultra-deep waters.

Deepwater and ultra deepwater drilling challenges

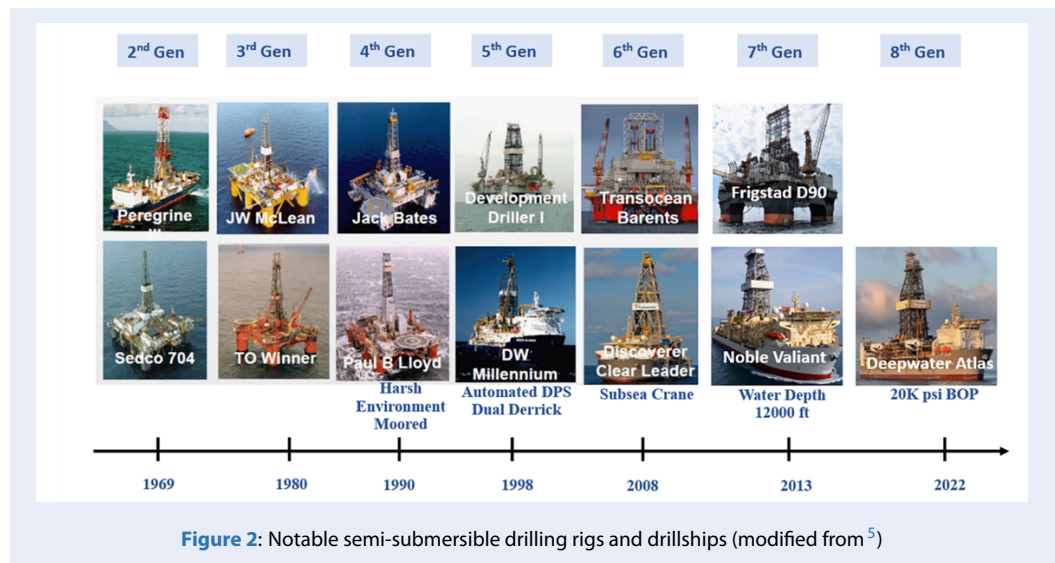

65 Although deepwater and ultra-deepwater drilling seg-
 66 ment has matured quickly and these wells have rapidly
 67 become a significant contributor of the world oil and
 68 gas supply (10.4 MMBOE/day in 2022) with an ex-
 69 pected 60% growth to over 17 MMBOE/day by the
 70 end of this decade⁶, there are huge inherent chal-
 71 lenges that are unique to its environment. Some of
 72 the unique challenges, by no means exhaustive, can
 73 be categorized as follow:
 74
 75

Natural hazards

76 From risks to marine life with seismic acquisitions,
 77 subsea operations in deepwater and ultra-deepwater
 78 involved no natural visibility, changing currents at
 79 different depths, low temperature-high pressures near
 80 the seabed, all of which are not as frequently encoun-
 81 tered as in shallower water depth.
 82

83 The total darkness of deepwater can be overcome by
 84 using remotely operated vehicles (ROVs) to provide
 85 lights and visual support. However, even with ROVs
 86 being deployed, the cuttings released to the seabed
 87 while drilling the first riserless sections can cause mud
 88 clouds that totally obscure the view of the wellhead for
 89 a significant period of time.

90 A current above 2 knots (3.7 km/h) can cause many
 91 problems⁷. Currents can cause vortex induced vibra-
 92 tions (VIV) to the drilling riser, make wellbore re-
 93 entries and setting subsea blowout preventer (BOP)
 94 and lower marine riser package (LMRP) and Christ-
 95 mas tree operations difficult and extremely risky to

96 the integrity of the well. An unplanned drive-off
 97 might occur as the drilling rig loses its ability to keep
 98 its position above the drill site. In the worst case, this
 99 will require an emergency disconnect (ED) to separate
 100 the wellhead from the drilling rig. However, normally
 101 only near surface current velocity and direction are
 102 recorded by the monitoring system.

103 The shallow layers below the sea bed are commonly
 104 unconsolidated or very weakly compacted. Under low
 105 effective stress, shallow water flows (SWF) can occur
 106 during the riserless drilling sections, especially with
 107 jetting operations. This geohazard can severely affect
 108 the integrity of the deepwater hole being drilled.

109 Finally, for deepwater and ultra deepwater, the hydro-
 110 static pressure is very high, while the water tempera-
 111 ture is very low (around 4°C, or 39-40°F). These low
 112 temperature-high pressure conditions are conducive
 113 to the formation of hydrates, which in turn can easily
 114 plug the drilling pipe and/or subsea BOP.

115 **Operational hazards**

116 The construction of a deepwater and/or ultra deepwa-
 117 ter well also poses many technical challenges besides
 118 the natural hazards. The vast distance between the
 119 drill site and shore, ocean winds, and high seas make
 120 logistics arrangements from the supply base very dif-
 121 ficult. For efficient operations at remote locations,
 122 drilling rigs are required to be self-reliant with as
 123 much supply stocked and ready as possible. More-
 124 over, the distance also negatively affects emergency
 125 responses.

126 The deeper the water, the longer and heavier the drill
 127 string, the casing string, and the riser become. Re-

spectively, they in turn require higher drill pipe spec- 128
 129 ifications, using heavier landing strings, and equip-
 130 ping riser tensioner with higher capacity to handle the
 131 higher tensile loads.

132 The high pressure, low effective stress conditions
 133 mean the required BOP pressure rating to guarantee
 134 safe drilling operations is also very high. The stan-
 135 dard BOP rating of deepwater well control system is
 136 103 MPa (15k psi) for 7th generation drilling rigs,
 137 and 138MPa (20k psi) for the newest 8th generation
 138 drillships. Figure 3 shows the evolution of the subsea
 139 BOPs over the years, with the current size and weight
 140 being almost triple the size and weight of BOPs 20
 141 years ago.

142 All these additional weights, from riser, BOP, and
 143 casing results in new axial load bearing capacity and
 144 bending moment requirements for the well founda-
 145 tion, namely the conductor and surface hole sections.
 146 The standardized size of conductor casing has domi-
 147 nantly become 91.44 cm (36 inches) with setting shoe
 148 depths ranging from 250 ft to 300 ft BML. Despite this
 149 setting, many deepwater and ultradeepwater wells still
 150 failed and had to be abandoned due to instability be-
 151 cause the well total weight exceeded the conductor
 152 casing loading capacity^{9,10}.

153 Finally, in order to save tripping times for operations
 154 like bit changes, running in casing, dual-derricks that
 155 allow dual activities were developed since the 5th gen-
 156 eration drilling rigs. For safe and efficient operations
 157 at this level of complexity, crew competency and com-
 158 munication among drilling crew - marine crew - and
 159 ROV crew are essential.

Figure 3: Deepwater and ultra deepwater subsea BOP and LMRP size and weight change over the year⁸

160 **Deepwater drilling cost**

161 In order to overcome these aforementioned chal- 188
 162 lenges, operators have to pay prices at the highest level 189
 163 to drill wells in deep- and ultradeep waters. The ma- 190
 164 jority of the total well cost is the day rate paid to 191
 165 the drilling contractors for the services of their top- 192
 166 of-the-art drilling rigs and crews. The remainder is 193
 167 costs for site survey, rig moves, tangibles, intangibles, 194
 168 and miscellaneous items. While shallow water wells 195
 169 may allow loggings and completions to be done offline 196
 170 (e.g. by utilizing a much cheaper intervention and 197
 171 completion unit (ICU) placed on a service vessel), for 198
 172 deep and ultra-deepwater, all activities, from dry-hole 199
 173 drilling, formation evaluation, to completion need to 200
 174 be done with the drilling rig. Therefore, the total cost 201
 175 can be up to 100 million dollars for a well. This great 202
 176 cost depends heavily on the time to drill the well, and 203
 177 especially the dayrate. 204

178 The time to drill a well depends on the rig move, the 205
 179 total drilling depth and well complexities. Rig move 206
 180 refers to the relocation of the drilling rig to the drill 207
 181 site, which might require moving across the oceans. 208
 182 With the latest generation rigs, the total drilling depth 209
 183 can be more than 12 km (40,000 ft) long. Cou- 210
 184 pled with complex well designs to overcomes various 211
 185 drilling challenges, drilling operations could take a 212
 186 few months to reach the well's target depth. The fa- 213
 187 mous and ill-fated Macondo well took BP more than 214

188 six months and two rigs to drill and complete, before 189
 190 the blowout occurred and resulted in a massive dis- 191
 192 aster to the well, the drilling rig Deepwater Horizon, 193
 194 the drilling crew, and the natural environment of the 195
 196 Gulf of Mexico¹¹. 197

198 The day rate for drilling rigs capable of drilling ultra- 199
 200 deepwater wells is the highest compared to other types 201
 202 of drilling rigs. In the early 2010s when 7th genera- 203
 204 tion rigs just came out, operators might have had 205
 206 to pay a day rate at around 1 million US dollars a 207
 208 day. The day rate plummeted during Covid-19 pan- 209
 210 demic, as oil demand and oil prices dropped to record 211
 212 levels, prompting companies to cut production, stop 213
 214 drilling as deepwater and ultra-deepwater prospects 215
 became uneconomic¹². Figure 4 shows the average 216
 day rates and total contracted utilizations of drillships 217
 and semisubmersible that are capable of drilling ultra- 218
 deepwater wells in the last three years¹³. The average 219
 day rate for an ultra-deepwater drillship fell below 200 220
 thousand US dollars in late 2020 and early 2021 while 221
 day rates for a semi-submersible were lower than 150 222
 thousand US dollar. However, the day rates have 223
 bounced back strongly since then, reaching close to 224
 500 thousand US dollars a day in the latest reports¹³. 225
 As day rate accounts for approximately half the total 226
 cost to drill the well, similar wells can have very dif- 227
 ferent cost, depending on the oil price forecast when 228

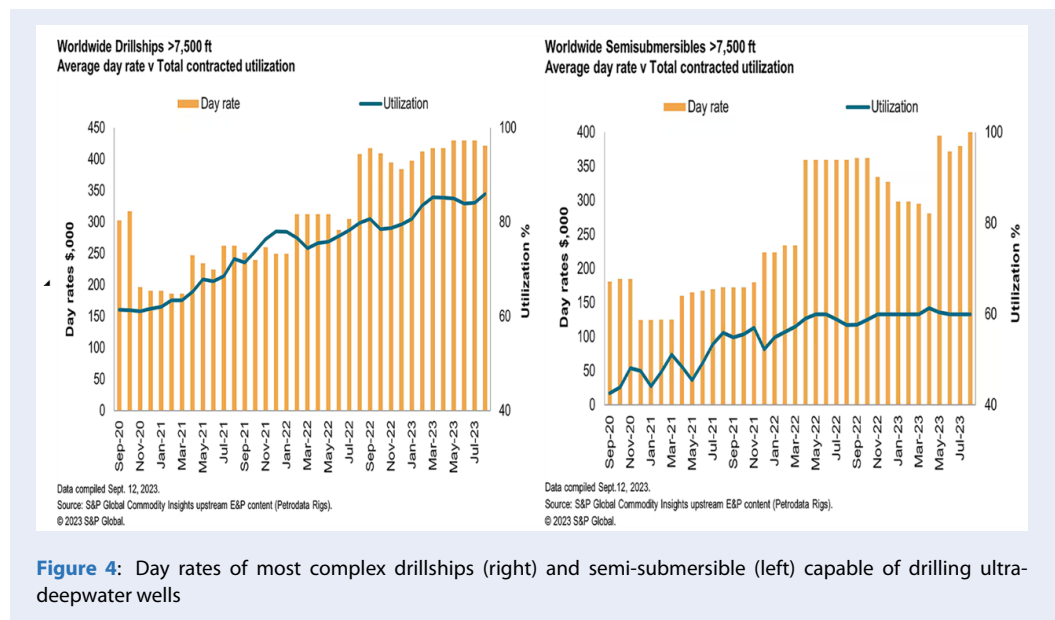

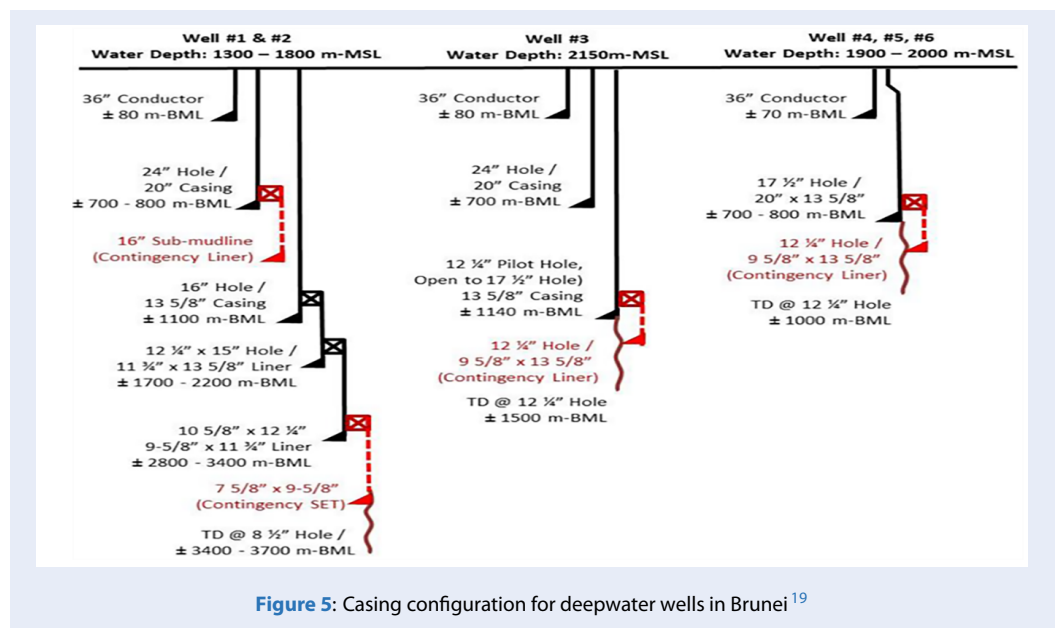

Figure 4: Day rates of most complex drillships (right) and semi-submersible (left) capable of drilling ultra-deepwater wells

215 an operator signs the drilling contract and how many
216 idle rigs are available at that time.

217 **Deepwater well designs**

218 The high well cost is one of the main contribu-
219 tors to the high break-even prices for deepwater and
220 ultra-deepwater projects. As a result, deepwater and
221 ultra-deepwater projects that are worth considering
222 must have significant reserves to justify development.
223 Then, the development strategy is that only a few
224 numbers of development wells in a deepwater and
225 ultra-deepwater field will be drilled to drain the res-
226 serves, in the shortest possible time. The number of
227 producers is significantly less compared to those in
228 onshore and/or shallow waters. Therefore, deepwater
229 and ultra deepwater wells must be designed that allow
230 high drawdown for high production rates¹⁴. In Brazil,
231 Petrobras is currently producing 2.2 million barrels of
232 oil equivalent per day from 152 deepwater wells tar-
233 geting pre-salt reservoirs¹⁵, or an average of over 14
234 thousand BOEPD per well. Another strategy to save
235 drilling cost is that, when an exploration deepwater
236 well is found to be successful, operators would very
237 frequently employ the temporary abandonment prac-
238 tice so that the well can be re-completed and turned
239 into a producer once the production system is ready.
240 As a result, the well designs are quite similar between
241 exploration and development (production) wells.
242 The high production rate requirement leads to the de-
243 velopment and adoption of big bore well designs for
244 deepwater and ultra-deepwater wells. Designing the
245 well from the bottom up, the smallest hole section at

246 the bottom will need to accommodate a production
247 casing string or liner whose diameter is at least 24.45
248 cm (9 5/8 inches). Above that, a varying number of
249 intermediate casing or liner sections would then have
250 diameters between 11 3/4” to 18”, isolating and protect-
251 ing the well from problematic zones like salt, weak,
252 and/or overpressured formations. Finally, at the top,
253 two (sometimes three) sections of conductor and sur-
254 face casings are needed to serve as the well founda-
255 tion. The standard deepwater conductor casing there-
256 fore is 36 inches in diameter, while diameters of sur-
257 face casings vary from 20 to 28 inches^{9,10,16-18}. These
258 diameters are 1.5 to 2 times bigger than typical con-
259 ductor and surfaces casings for onshore wells.
260 The standard, normal design for Gulf of Mexico deep-
261 water wells has 6-7 casing-liner sections while for
262 deeper wells, tight-clearance designs with 8-9 sections
263 might be required¹⁷. For reservoirs that are only
264 1,000m (3,300ft) below mudline, a “slimhole” design
265 with 3 hole sections can be adopted^{16,19}. Figure 5¹⁹
266 shows different well designs for ultra-deepwater wells
267 in Brunei, South China Sea, highlighting the innova-
268 tions to simplify well structure to reduce the well cost.
269 To complete deepwater and ultra deepwater wells,
270 cased hole fracpack (CHFP) is the preferred method
271 as it can provide long-term protection to the bore-
272 holes, especially when the producing reservoirs are
273 weakly consolidated or unconsolidated²⁰. For more
274 competent reservoirs, open hole gravel pack (OHGP)
275 and open hole fracpack (OHFP) options are some-
276 times considered, as they allow higher rates and re-
277 duce completion time and cost²¹. However, when ei-

278 ther open hole completion method is chosen, the risk
279 of wellbore instability must be carefully evaluated.

280 VIETNAM DEEPWATER POTENTIAL 281 AND CHALLENGES

282 Vietnam deepwater basins and oil and gas 283 exploration status

284 In Vietnam, there are several sedimentary basins with
285 vast unexplored deepwater areas, namely Phu Khanh
286 basin, Tu Chinh-Vung May basin, Hoang Sa basin and
287 Truong Sa basin. The U.S. Energy Information Ad-
288 ministration, in 2019 estimated that Vietnam oil and
289 gas proved and probable reserves stand at about 3.0
290 billion barrels of oil and 20 trillion cubic feet of gas²².
291 However, undiscovered resources in deepwater areas
292 can be much greater.

293 In these four deepwater basins, both well and seis-
294 mic data are sparse. Most recently, 14,500 line km
295 of multi-client 2D seismic, gravity and magnetic data
296 were acquired for Phu Khanh basin in 2008, which
297 helped enable exploration studies and very first deep-
298 water drilling activities in this basin²³. The first Viet-
299 nam true deepwater well TB-1X at over 1,600m wa-
300 ter depth, was drilled in 2015 in block 131 but it was
301 unsuccessful in finding commercial oil or gas accu-
302 mulations. The other well, TD-1X in block 130, was
303 drilled at over 1,000m water depth and was also a dry
304 hole. Thus, deepwater hydrocarbon potential assess-
305 ments still rely mainly on interpretations of available
306 seismic lines from which major sequences and struc-
307 tures have been identified.

In Phu Khanh basin, basin studies and recent well re- 308
sults in shallow water have confirmed its positive hydro- 309
carbon potentials, with oil presence and existence 310
of both structural and non-structural traps^{24,25}. Shal- 311
low gas signatures from seismics data have also been 312
identified and interpreted as hydrate sources in the 313
deepwater areas - the eastern part of the basin²⁶. 314
Tu Chinh-Vung May basin has a large region where 315
water depth exceeds 1,000m, but only a handful of 316
2D seismic lines are available for the deepwater re- 317
gions²⁷. In Hoang Sa basin, many gas fields, includ- 318
ing several giant deepwater fields in over 1,500m wa- 319
ter depths were discovered and developed illegally by 320
China^{28,29}. In Truong Sa basin, little exploration ac- 321
tivities were conducted due to tense maritime dispute 322
among countries in the region. 323

324 Vietnam deepwater challenges

Nowadays, advanced deepwater and ultra-deepwater 325
technologies and know-how are dominated by the 326
United States, Brazil, and Norway, while China is 327
catching up very quickly with massive investments 328
over the last ten to fifteen years. On the other hand, 329
at this point, Vietnam's capability on its deepwater is 330
still very limited. There is a total lack of experience, 331
facilities, and understanding of deepwater and ultra- 332
deepwater technology. Seafloor topography, shallow 333
soil conditions, sea waves and currents patterns, hy- 334
drates accumulations, as well as and prediction of ex- 335
treme weather conditions like typhoons are things 336
that need to be studied further for deepwater areas. 337

338 In order for Vietnam to reverse the situation, govern-
 339 mental strategy, policy as well as financial supports
 340 are clearly needed. Deepwater surveys and 2D and
 341 3D seismic acquisitions will be needed in order to
 342 have a better estimation understanding of the envi-
 343 ronment and the subsurface of these basins. Facili-
 344 ties such as geological survey vessels, supply vessels,
 345 floating drilling rigs (semi-submersibles and/or drill-
 346 ships), construction yards and bases for maintenance
 347 and supply will need to be established. Finally, in-
 348 ternational partnerships, collaborative academic and
 349 industry research in deepwater technologies, from
 350 exploration, drilling and completion, to flow assur-
 351 ance, development strategies, from design to opera-
 352 tions should be encouraged and pursued.

353 CONCLUSIONS

354 The definitions of deepwater and ultra-deepwater
 355 have progressively evolved in the last fifty years, and
 356 this segment's contribution and importance to the
 357 world oil and gas supply have been increasing at
 358 an exponential rate. Modern floating drilling rigs
 359 - semi-submersibles and drillships - are currently at
 360 their 7th and 8th generations, and are capable of
 361 drilling wells at locations up to 12,000ft in water
 362 depth. To overcome its various challenges and ex-
 363 pensive drilling costs, many of which are unique only
 364 to deepwater and ultra-deepwater, a completely new
 365 line of technologies for well structure (big bore sys-
 366 tem), safety measures (15k-20k BOP), subsea equip-
 367 ment and drilling-completion-production practices
 368 have been developed and continuously refined.

369 Vietnam has four deepwater and ultra-deepwater
 370 basins with large unexplored areas and high estimates
 371 of undiscovered resources, although dry deepwater
 372 wells were drilled in Phu Khanh basin. At the mo-
 373 ment, Vietnam's capability in deepwater oil and gas
 374 segment is severely limited, and it would require a to-
 375 tal collaborative effort from the government, the in-
 376 dustry, the academia to reverse the situation.

377 ACKNOWLEDGEMENT

378 We acknowledge Ho Chi Minh University of Tech-
 379 nology (HCMUT), VNU-HCM for supporting this
 380 study.

381 CONFLICT OF INTEREST

382 The authors certify that this article is a research work
 383 of the authors and has not been published elsewhere.
 384 It did not copy previous research articles; There is no
 385 conflict of interest for any individual, any agency or
 386 organization.

AUTHORS' CONTRIBUTION

The article ideas were contributed and supervised by
 Trung Dung Tran. Le Nguyen Hai Nam provided
 guidance and analyzed solutions suitable for Vietnam.
 Nguyen Quoc Minh, Huynh Mai Tra and Luu Thi
 My Duyen collected data, did analyses, and wrote the
 manuscript.
 All authors have read and approved the final
 manuscript.

TÓM TẮT

Bài viết này cung cấp cái nhìn tổng quan về những thay đổi trong định nghĩa nước sâu và nước siêu sâu, sự phát triển của giàn khoan, việc thiết kế giếng, công tác khoan và hoàn thiện giếng, cũng như các thiết bị để vượt qua hàng loạt khó khăn thách thức đặc thù và chi phí khoan cao. Việc khoan và phát triển dầu khí ở vùng nước sâu và nước siêu sâu đã tồn tại hơn 60 năm và ngày càng trở nên quan trọng đối với ngành dầu khí toàn cầu. Với mỗi tiến bộ trong công nghệ, chúng ta có thể khám phá và khai thác hydrocarbon ở xa hơn, ở độ sâu nước sâu hơn, và do đó định nghĩa về nước sâu và nước siêu sâu đã được viết lại nhiều lần. Phần khúc này của ngành dầu khí đã có mức tăng trưởng và số lượng đổi mới cao nhất nhờ nhiều phát hiện dầu khí khổng lồ ở vùng nước sâu và phát triển chúng thành các mỏ khai thác ở Vịnh Mexico, Brazil, Biển Bắc, Tây Phi và nhiều nơi khác trên khắp thế giới. Việc ngày càng nhiều giếng được khoan ở độ sâu ngày càng tăng khiến các thách thức khoan, bao gồm cả các mối nguy hiểm tự nhiên và vận hành đều tăng theo cấp số nhân, dẫn đến các yêu cầu kỹ thuật ngày càng nghiêm ngặt hơn để vận hành an toàn. Những điều này đang được đáp ứng bởi sự phát triển nhanh chóng và phức tạp của hệ thống chống phun trào BOP và tàu khoan qua nhiều thế hệ, tối ưu hóa thiết kế giếng khoan nước sâu với thân giếng lớn cũng như các ứng dụng khoan và hoàn thiện, điều hướng hàng hải, công nghệ và quy trình vận hành các thiết bị điều khiển từ xa ROV, cũng như việc chia sẻ các bài học kinh nghiệm. Điều này thể hiện sự quan tâm không ngừng của ngành dầu khí cho phép khai thác tài nguyên từ môi trường nước sâu và siêu sâu, đặc biệt khi phải đối mặt với rủi ro cao và chi phí đầu tư cao cho các dự án nước sâu và siêu sâu, trong đó có thể kể đến chi phí khoan rất cao. Trong phần thứ hai, bài viết xem xét tiềm năng hydrocarbon nước sâu và nước siêu sâu của Việt Nam, hiện trạng và những thách thức, đồng thời đề xuất các bước cần thiết để có thể giúp Việt Nam khai thác nguồn tài nguyên hydrocarbon khổng lồ chưa được khám phá này.

Từ khoá: Khoan nước sâu, sự tiến bộ trong thi công khoan và thiết kế giếng, khoan nước sâu ở Việt Nam, thực trạng khoan nước sâu ở Việt Nam, thách thức cho Việt Nam, bài học cho Việt Nam
