ABSTRACT

The construction of an integrated information system to support command and control to meet the requirements of national defense in wartime and peacetime is extremely urgent. In order for this system to be effectively applicable, it is necessary to ensure both the necessary and sufficient conditions. The primary necessary condition is the system's applicability, while the sufficient condition encompasses the complementary measures and solutions within the system to ensure its integrity, authenticity, and robustness. The system is deployed in the Command Post's private network environment, this is the network layer that needs protection and is not connected to the internet. The network system is divided into two parts: secret network and clear network. The secret network contains data of the entire system, so it is necessary to control all connections to this secret network. The clear network can connect to external networks through system information security control devices. To fulfill the system requirements, a comprehensive approach is essential, involving both engineering and personnel aspects. However, within the scope of this article, the authors primarily present a set of hardware solutions aimed at addressing the issue of information protection. This article identifies groups of information that require protection, mitigates security threats, and highlights the existing hardware tools that are suitable for the established operating management system model. The goal of the solution is to ensure absolute information security of the system when deployed in military units. By using experimental methods, analyzing and summarizing experience during the installation and testing process in the laboratory and in practice at the deploying unit, we have achieved the effectiveness of ensuring information security. according to military requirements. However, using this solution will increase the delay in information exchange between devices.

Key words: operating management system, information protection, hardware security solutions

1 INTRODUCTION

2 The emergence and strong development of science
3 and technology, especially the 4.0 technological revo-
4 lution, have significantly changed the theoretical and
5 practical aspects of military affairs and altered the
6 methods of conducting warfare, the dimensions of
7 space and time in combat, and even the boundaries
8 of offense and defense. The general trend worldwide
9 is to build efficient and streamlined armed forces, and
10 the automation of command is an inevitable histor-
11 ical necessity to address the contradiction between
12 the increasing volume of various types of information
13 reaching the advisory and command agencies, which
14 becomes larger, more complex, and more frequent,
15 and the demand of modern warfare for information
16 to be processed in the shortest possible time, in real-
17 time.
18 In parallel with this trend, within the country, vari-
19 ous systems serving the management and operation of
20 Command Posts have been researched and equipped,

such as the combat command support system, the on- 21
line briefing system, the security surveillance cam- 22
era system. However, these systems operate indepen- 23
dently and need to be integrated into a coherent sys- 24
tem, lacking the ability to transmit combat informa- 25
tion in the form of images and videos and not allowing 26
direct connections to seek guidance from leadership. 27
Therefore, there is a need to integrate these indepen- 28
dent information systems into a unified integrated 29
system that has the capability to connect and share 30
data to serve the processing of defense scenarios at 31
the Command Post in order to successfully accom- 32
plish national security tasks¹. However, the issue of 33
security and information protection in this integrated 34
system needs to be addressed to prevent the leakage 35
of combat information from the Command Post to 36
the integrated systems. In addition to software solu- 37
tions for data encryption, the solution of using hard- 38
ware devices to transmit and receive one-way data is 39
a promising avenue for research and investment. 40

41 In this article, the application of one-way data trans-
42 mission devices within the integrated information
43 system equipped at the Military Command Head-
44 quarters of the Provincial Military Command¹ will be
45 presented.

46 RESEARCH METHODS

47 - Use theoretical analysis and synthesis methods; An-
48alyze actual system requirements.

49 - Research documents, risks, and security solutions at
50 home and abroad.

51 - Analyzing and summarizing experience to provide
52 communication solutions to connect the system and
53 security solutions, information security of the system.

55 INTEGRATED INFORMATION 56 SYSTEM AND HARDWARE SECURITY 57 SOLUTIONS FOR THE SYSTEM

58 General Introduction to the Operational 59 Management System

60 The command and control system is located at the
61 Provincial Military Command Headquarters, specif-
62 ically implemented at the Command Office of the
63 Provincial Military Command and two subordinate
64 units. The system's task is to support command and
65 control activities at various levels of command offices
66 during regular operations as well as in emergency sit-
67 uations. The system allows for the connection of de-
68 vices placed in different command offices, with the
69 capability to transmit and receive important informa-
70 tion that requires high security. In particular, the
71 system enables the connection to existing informa-
72 tion systems within the province's territory in cases of
73 defense emergencies, facilitating seamless command
74 and control operations. With this function, the sys-
75 tem needs to establish connectivity with the network
76 systems of the establishments to be connected within
77 the province's territory, and the primary task is to en-
78 sure the security and protection of information along
79 this connection pathway.

80 The operational model of the management and oper-
81 ating system is depicted in Figure 1. The significant
82 task of the solution presented in the article aims to
83 propose a hardware solution to ensure the secure pro-
84 tection of information throughout the entire system.

85 The issue of information protection in the 86 integrated system

87 To build a system aimed at safeguarding information,
88 it is necessary to consider the following solutions²:

- Installing and configuring the database: Organizing 89
a rational network architecture and setting up defense 90
systems help administrators gain an overview of their 91
unit's entire network model. Through this, they can 92
organize a sensible network model and establish es- 93
sential defense systems such as firewalls, intrusion de- 94
tection/prevention devices (IDS/IPS). 95

- Installing protective applications: In addition to 96
troubleshooting system components, this content ad- 97
dresses the installation of protective applications such 98
as antivirus systems and host-based intrusion detec- 99
tion systems (HIDS) to proactively and comprehen- 100
sively safeguard electronic gateways/websites. 101

- Establishing backup and recovery mechanisms: 102
Setting up regular backup mechanisms for the 103
system aims to preserve operational states when 104
the system is functioning smoothly. These 105
backup copies will be utilized in the event of sys- 106
tem error inspection or system recovery to the 107
state prior to being compromised in cases where 108
the errors are irreparable or cannot be fixed. 109

Applied to the established system model¹, the author's 110
team proposes the following solution groups^{3,4}: 111

- For the military data transmission network connec- 112
tion, the issues of security, confidentiality, and system 113
safety are under the responsibility of the Cipher com- 114
mittee. 115

- For the wide area network (WAN) connection of the 116
Command Office, the system is deployed based on 117
the transmission project established by the Provincial 118
Military Command, and the issues of security, confi- 119
dentiality, and system safety (RCY) constitute a com- 120
ponent of this project. 121

- For the network connection of Committees, Depart- 122
ments, Boards, Sectors, and Police, a one-way data 123
transmission solution is employed for both inbound 124
and outbound directions. The system is designed 125
to ensure grounding, prevent the spread of lightning 126
strikes, and has the capability to isolate the system 127
in case of incidents while restoring the initial state of 128
the Command Office before the installation of equip- 129
ment. 130

- In terms of hardware, utilize router firewall de- 131
vices at the output ports of the system equipment at 132
each Command Office, configuring the packet filter- 133
ing rules of these devices to allow permitted applica- 134
tions to pass through. Set up blacklist and whitelist 135
configurations to either allow or block specific ad- 136
dresses within the WAN network 137

- As for software solutions, a group of solutions is em- 138
ployed, including the use of antivirus software utilized 139

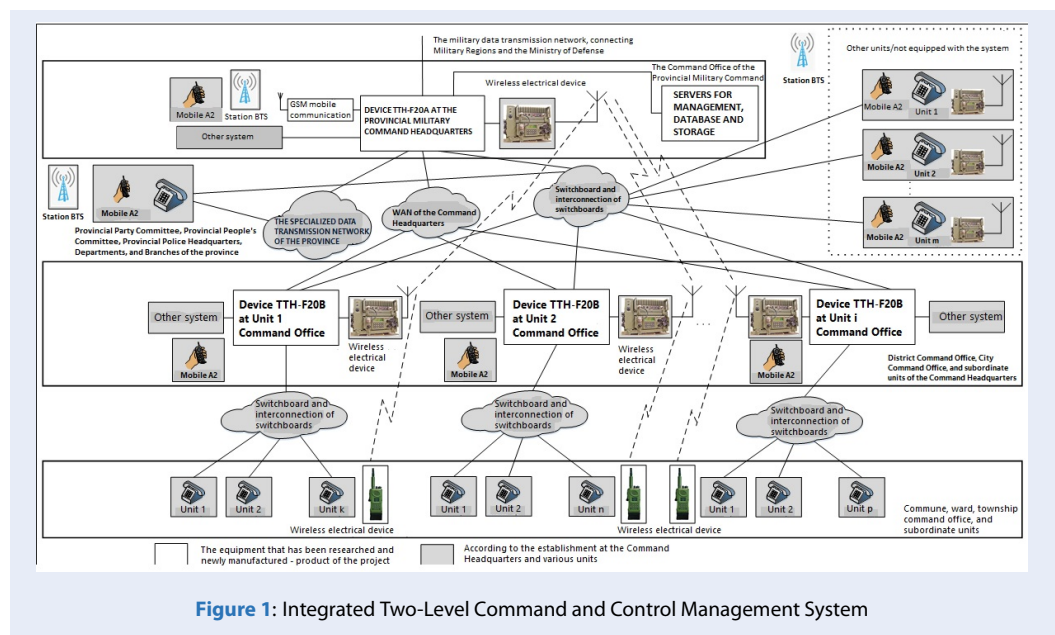

Figure 1: Integrated Two-Level Command and Control Management System

140 in the military. The authors of the article establish
 141 information security regulations within the real-time
 142 software execution of virus protection, implement au-
 143 thorization mechanisms for functionalities, and seg-
 144 regate data access permissions within the system to
 145 align with the unit's requirements. Access to the sys-
 146 tem is regulated by granting access privileges accord-
 147 ing to specific roles, allowing access to critical func-
 148 tions only through corresponding login credentials
 149 with appropriate permissions.

150 - Information stored within the system is encrypted,
 151 not stored in plain text, to prevent direct informa-
 152 tion loss scenarios within the system. Textual and
 153 visual information, before being transmitted or re-
 154 ceived through the system, must pass through the In-
 155 formation Committee to ensure that information is
 156 managed by the Information Committee, and then
 157 it goes through the Cipher Committee to ensure secu-
 158 rity as managed by the Cipher Committee. Encryp-
 159 tion/decryption can be carried out as required
 160 by the information recipient. For critical informa-
 161 tion such as Command Codes, alarm data, and com-
 162 bat readiness status updates, devices perform encryp-
 163 tion/decryption before transmission, utilizing sym-
 164 metric encryption techniques. The key distribu-
 165 tion center is managed by the Provincial Military
 166 Command's equipment, and the keys are securely
 167 distributed to user units via public-key encryption.
 168 There is a mechanism for tracking the usage, access,
 169 and exchange of information by user accounts logging
 170 into the system.

Hardware solution using one-way data transmission devices

171
 172
 173 With the system model depicted in Figure 1, it's read-
 174 ily apparent that the network connections within the
 175 system can be effectively divided into two distinct
 176 subnetworks: the trusted network and the untrusted
 177 network. The trusted network serves as the dedi-
 178 cated network for connecting the system components
 179 within the Command Office, and between various
 180 levels of Command Offices, utilizing the military's
 181 private network. The untrusted network encom-
 182 passes the network systems of local agencies, Provin-
 183 cial Party Committees, and sectors. The primary im-
 184 perative is to enable the system to establish connec-
 185 tions and facilitate data transmission to and from the
 186 untrusted network while still ensuring the absolute se-
 187 curity of the trusted network. The utmost priority is to
 188 prevent any occurrences of data loss or unauthorized
 189 data transfer from the trusted network, ensuring no
 190 data leakage into the untrusted network.

191 From the specific requirements mentioned above, it's
 192 imperative to introduce protective barriers between
 193 the trusted and untrusted networks. There are two ap-
 194 proaches in ensuring the system's security⁵.

195 Building on Explicit Policies: This approach involves
 196 enforcing safety measures such as unifying the in-
 197 stallation of secure applications on the system, coor-
 198 dinating with OS/software providers to request offi-
 199 cial patches, closing unused ports/services on the sys-
 200 tem, controlling/monitoring device access, and limit-
 201 ing continuous remote connections.

202 Proposing a Novel Technological Solution: This ap-
 203 proach introduces a security device known as Data
 204 Diode. This physical one-way data transmission secu-
 205 rity device offers a deployment option to ensure qual-
 206 ity of service and security⁶.
 207 The authors have developed the system with sensi-
 208 tive and critical data that require isolation, yet must
 209 also maintain an access authorization policy for au-
 210 thorized users, which can lead to network attack vul-
 211 nerabilities. The solution the authors have opted for is
 212 using the Data Diode security device that only allows
 213 one-way information flow, making it impervious to
 214 network attacks.
 215 Data Diode devices are most commonly employed
 216 in control and automation systems, bank data cen-
 217 ters, and military systems. This solution is deployed
 218 through two primary models, aimed at preserving the
 219 fundamental attributes of a system⁵.
 220 Receive – Only – High – Confidentiality Configura-
 221 tion: This configuration maintains the system’s secu-
 222 rity by solely accepting data. In a protected state, the
 223 system exclusively receives data from other systems,
 224 with no data transmitted in reverse. Potential attacks
 225 or exploitation attempts could be directed at the se-
 226 cured network. However, no information from this
 227 network can be sent back to the external network.
 228 Transmit – Only – High – Availability Configuration:
 229 This configuration ensures the system’s availability by
 230 only transmitting data. In a safeguarded state, the sys-
 231 tem solely sends data to other systems and does not
 232 accept any incoming data from other systems. Con-
 233 sequently, the protected network cannot be remotely
 234 scanned, attacked.
 235 Figure 2 is a diagram that specifically describes how
 236 the data diode device works. Accordingly, for OT
 237 Network networks, the data diode plays the role of a
 238 data control device in the transmit-only direction, and
 239 for an IP/CORP network, the data diode device plays
 240 the role of a data control device in the receive-only di-
 241 rection.
 242 The choice of hardware security solution depends on
 243 the characteristics of each specific system. For mili-
 244 tary command and control systems, the primary ob-
 245 jective is to absolutely prevent any leakage of infor-
 246 mation from the system. Guided by this criterion, the
 247 authors opt for a solution that combines various mea-
 248 sures, prominently featuring the utilization of one-
 249 way data transmission devices in the communication
 250 path to receive data from the trusted network into the
 251 untrusted network. The one-way data transmission
 252 device is researched with a focus on ensuring secure
 253 remote access. Employing this device in the system
 254 entails the following advantages and disadvantages:

- Advantages: 255
- + Ensures security segregation between networks. 256
- Network segregation is one of the most effective ways 257
- to safeguard networks. 258
- + Prevents configuration errors that might allow ma- 259
- licious applications to be granted access to the system. 260
- + Low maintenance costs, as configuring a data diode 261
- is straightforward and doesn’t require a highly skilled 262
- administrator to maintain the system. 263
- + Data Diode enables real-time data transmission in 264
- high-security environments. 265
- Disadvantages: 266
- + Data diode equipment can be quite expensive. 267
- + Using Data Diodes means allowing only one-way 268
- communication for certain applications, such as those 269
- built on UDP protocol. This necessitates having two 270
- data diode devices for transmission and reception, 271
- limiting the packet size and reducing transmission 272
- speeds. 273
- In summary, comparing the pros and cons above with 274
- the system management requirements, Data Diodes 275
- emerge as a favorable solution capable of addressing 276
- the challenges posed by the authoring team. 277
- 1 RESULTS AND DISCUSSION** 278
- Figure 3 introduces the network connection and se- 279
- curity diagram in the integrated system that the au- 280
- thors implemented at the provincial military com- 281
- mand. Through the integrated information system 282
- model that has been developed¹, the system can be 283
- divided into two components: the internal network and 284
- the external network. Accordingly, the internal net- 285
- work represents the network of the provincial military 286
- command, while the external network is the special- 287
- ized data transmission network of the province, con- 288
- connected to the Provincial Party Committee, the Provin- 289
- cial People’s Committee, various departments, and 290
- the provincial police. 291
- In order to integrate these two network systems to 292
- serve the command and control operations, the au- 293
- thors of this study have constructed a model of an 294
- integrated network system using one-way data trans- 295
- mission devices known as Data Diodes. The informa- 296
- tion and data within the internal network will be se- 297
- cured through this solution, in combination with sev- 298
- eral other measures such as utilizing firewall devices, 299
- installing and configuring secure servers, establishing 300
- and configuring secure databases, encrypting stored 301
- data, encrypting data in transmission, and employing 302
- official operating systems/software with patches from 303
- manufacturers. Additionally, the security solutions 304
- provided by essential agencies will also be incorpo- 305
- rated. 306

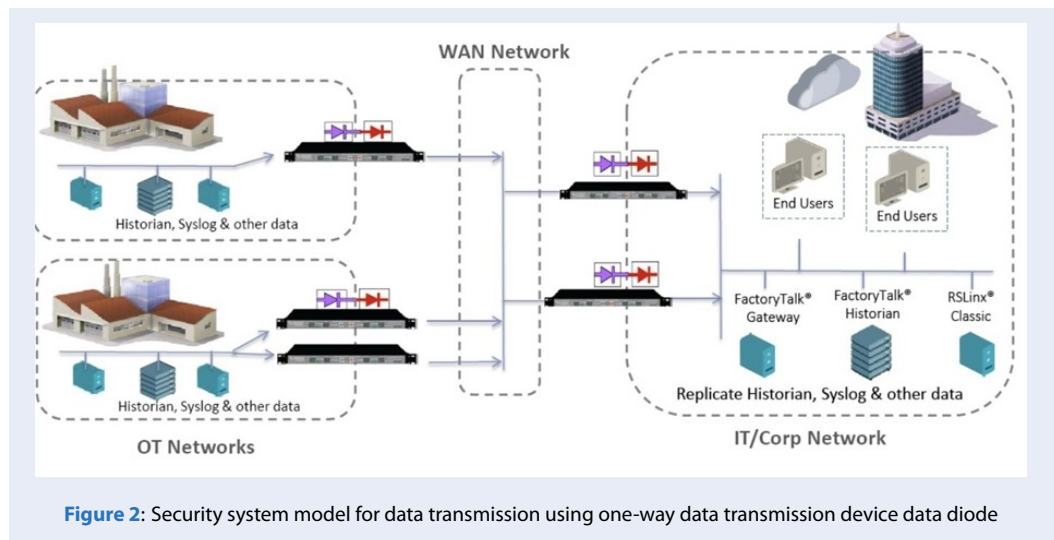

Figure 2: Security system model for data transmission using one-way data transmission device data diode

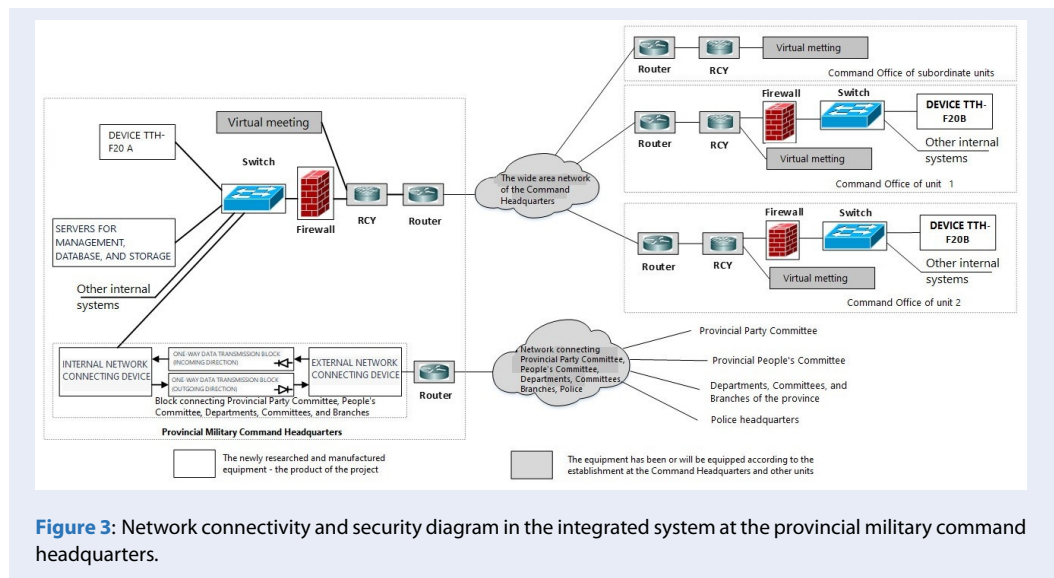

Figure 3: Network connectivity and security diagram in the integrated system at the provincial military command headquarters.

- 307 Outcome of building a One-Way data transmission
- 308 solution for the system with the following parameters:
- 309 Functions of the One-Way data transmission device:
- 310 - Automatically transmit unidirectional data from the
- 311 sending side.
- 312 - Automatically transmit unidirectional data from the
- 313 receiving side.
- 314 - Monitoring and control function for transmission
- 315 flow.
- 316 - Packet status monitoring function.
- 317 - Statistical function for monitoring the number of
- 318 transmitted and received files.
- 319 - Web user interface.
- 320 - Allow users to upload and download data files
- 321 through the web interface.
- Data integrity assurance function.
- All transmitted data is accompanied by a SHA hash
- value to verify data integrity at the receiving end.
- Personal data security function.
- Each user is provided with a separate login account,
- and the storage space on the server is completely iso-
- lated.
- Supported protocols: UDP, FTP, SFTP, syslog.
- Scalability (Advanced Options):
- + Supported expansion protocols: RTP, Multicast
- UDP, Modbus, SMB, NTP, SMTP, SMTPS.
- + Expansion features: transmission of various file for-
- 333 mats, streaming, database replication.
- 334
- 335 Table 1 is the technical specifications of the equip-
- 336 ment that the authors installed at the provincial mili-

Table 1: Specifications of the Devices

No.	Devices	Configuration
1	Transceiver Unit	- Processing unit: Core i7 10710U upto 4.7GHz, 6 x12, 12MB cache. - Internal memory (RAM): 8GB DDR4 2666MHz. - Hard drive: SSD 256GB.
2	Optoelectronic conversion	- Transmission speed: 10/100/1000 Mbps. - Optical connection standard: SC, 03 fibers. - Internet connection standard: RJ45. - Transmission mode: Single Mode.
3	Connection port	- USB port 3.0: 04. - Ethernet port: 02 (reception and transmission). - HDMI port: 02.

337 tary command.

338 CONCLUSION

339 Based on the previously built information service in-
340 tegration system model¹, the authors used a hardware
341 security solution using a Data Diode one-way data
342 transmission and reception device.

343 We proposed to create a physically secure one-way
344 channel from the unsecured network to the secure
345 network, allowing data to be securely transferred into
346 the secure network. Not allowing any data to be trans-
347 ferred in the opposite direction ensures that strangers
348 cannot access the secure network from less secure ex-
349 ternal networks and greatly prevents data leakage.

350 Once the issue of security and information protection
351 in systems with connections between secure networks
352 and less secure networks is solved, it will promote the
353 ability to integrate systems of domestic units and or-
354 ganizations. That facilitates the formation of a unified
355 integrated system in the future, making information
356 retrieval and search more convenient. This problem
357 not only solves the problem of information transmis-
358 sion and reception between military units and outside
359 units, but also solves the problem of information pro-
360 tection for e-government.

Xây dựng giải pháp bảo mật dữ liệu tác chiến cho hệ thống quản lý điều hành tại sở chỉ huy

Trần Việt Dũng, Nguyễn Trúc Quyên, Cù Hoài Nam*

Use your smartphone to scan this QR code and download this article

TÓM TẮT

Bài toán xây dựng hệ thống tích hợp thông tin hỗ trợ công tác chỉ huy điều hành đáp ứng yêu cầu bảo vệ Tổ quốc trong thời chiến cũng như trong thời bình là vô cùng cấp thiết. Và để hệ thống đó có thể áp dụng trong thực tiễn thì cần đảm bảo cả điều kiện cần và điều kiện đủ. Điều kiện cần chính là tính ứng dụng của hệ thống, điều kiện đủ chính là các biện pháp, giải pháp đi kèm của hệ thống nhằm đảm bảo tính toàn vẹn, xác thực của dữ liệu, và đảm bảo dữ liệu không bị rò rỉ thất thoát ra khỏi hệ thống. Hệ thống được triển khai trong môi trường mạng riêng của Sở chỉ huy, đây là lớp mạng cần bảo vệ và không được kết nối internet. Hệ thống mạng được chia ra thành hai phần mạng mật và mạng rõ. Mạng mật chứa dữ liệu của toàn bộ hệ thống, do đó cần kiểm soát tất cả các kết nối đến mạng mật này. Mạng rõ có thể kết nối với các mạng bên ngoài thông qua các thiết bị kiểm soát an toàn thông tin hệ thống. Để đáp ứng các yêu cầu trên hệ thống cần có giải pháp tổng thể về kỹ thuật, về con người. Tuy nhiên trong phạm vi bài báo này, nhóm tác giả trình bày chủ yếu về nhóm các giải pháp phần cứng để giải quyết vấn đề bảo vệ thông tin. Bài viết này xác định các nhóm thông tin cần được bảo vệ, giảm thiểu các mối đe dọa bảo mật và nêu bật các công cụ phần cứng hiện có phù hợp với mô hình hệ thống quản lý vận hành đã thiết lập. Mục tiêu của giải pháp là đảm bảo tính an toàn thông tin tuyệt đối của hệ thống khi triển khai trong các đơn vị quân đội. Bằng các phương pháp thực nghiệm, phân tích và tổng kết lại kinh nghiệm trong quá trình cài đặt và thử nghiệm trong phòng thí nghiệm và thực tế tại đơn vị triển khai chúng tôi đã đạt được hiệu quả đảm bảo được tính an toàn thông tin theo đúng yêu cầu trong quân đội. Tuy nhiên, khi sử dụng giải pháp sẽ làm tăng độ trễ trong việc trao đổi thông tin giữa thiết bị.

Từ khóa: Hệ thống quản lý điều hành, bảo vệ thông tin, giải pháp an toàn phần cứng
